Curriculum Graph: Student-Centric Curriculum Planning with Dependency Analytics

Mini Project for DS3294: Data Science Practice

Ayush Raj Malhar Patel Sankar Maharajan Applen Tahu

April 4, 2026

1 Introduction

We developed *Curriculum Graph*, a student-centric dashboard for major/minor planning that combines prerequisite dependency analytics with an interactive UI. The system helps students understand course dependencies, validate program requirements, and plan feasible semesters under offering and credit constraints.

Curriculum planning is often difficult for students because prerequisite relationships, semester offerings, and major/minor rules are spread across multiple documents. A graph-based representation is naturally suited for this problem: courses are modeled as nodes and prerequisites as directed edges. Graph traversal, topological logic, and bottleneck analysis then become useful for practical advising and semester-by-semester planning [1].

The main challenge is not only algorithmic; it is also usability. Even a correct graph can be hard to use if the interface is cluttered or if required insights are buried in technical detail. We therefore combine backend graph analytics with a student-facing dashboard built in Streamlit [3] and yFiles for interactive graph rendering [4].

2 Problem Statement and Objectives

Our goal is to build a reproducible, policy-aware planning system that answers the following student questions:

- What should I take next semester given my completed courses?
- Which prerequisites are blocking my progress?
- Is my current pathway valid for my major and minor?
- Can I still reach the degree target under term constraints?

The concrete objectives are:

- Build clean dependency graphs with semester and year structure.
- Validate major/minor pathways against rule sets.
- Generate constrained semester plans (course and credit caps).
- Provide an accessible UI with student mode and advanced mode.
- Ensure reliability through testing, validation checks, and a clean modular code structure.

3 Methods

3.1 Data

The system uses three primary JSON inputs:

- Course catalog: course code, name, credits, subject, kind, prerequisites, and semester offerings.
- Major/minor requirement rules: set-wise constraints and exclusions.
- College constraints: number of semesters and minimum degree credits.

In the current snapshot, the dataset contains 264 courses, 9 subjects, and 16 major/minor criteria entries [2]. Data-health checks report no duplicate course codes, no missing prerequisite links, and no unknown requirement codes.

3.2 Implementation Summary

The final codebase is organized into clear modules:

- `src/app.py`: Streamlit dashboard and interaction logic.
- `src/graph.py`: graph construction, planning, and analytics utilities.
- `src/validate_major_minor.py`: rule validation and requirement checks.

This structure enabled a maintainable workflow where UI improvements and algorithmic improvements could be developed independently and then integrated.

3.3 Graph Modeling and Planning

We build a directed graph $G = (V, E)$ where V is the selected course set and E contains edges (u, v) whenever course u is a prerequisite of course v. The planning engine uses semester offerings and prerequisite satisfaction to select feasible courses term-by-term.

At a high level, the semester planner greedily selects available courses while respecting per-term caps and prioritizing compulsory requirements. The process is described in Algorithm 1.

For each course c, feasibility in semester s is defined by two conditions: offering availability and prerequisite satisfaction,

$$c \in \mathcal{O}(s), \tag{1}$$

$$\mathrm{pred}(c) \subseteq \mathcal{C}_{\mathrm{done}}, \tag{2}$$

where $\mathcal{O}(s)$ is the set of courses offered in semester s, and $\mathcal{C}_{\mathrm{done}}$ is the completed course set.

3.4 Dashboard Design

The dashboard has two usage modes:

- **Student mode**: fewer tabs, cleaner defaults, readable labels, and within-year arrow emphasis.
- **Advanced mode**: full algorithm diagnostics, rule explorer, validation internals, and quality views.

To reduce cognitive overload, graph legends are explicit, transition summaries are collapsible, and major/minor options are policy-filtered to approved offerings in the current deployment profile.

Table 1: Dataset and system summary statistics.

Metric	Value
Total courses	264
Program entries (major/minor)	16
Subjects covered	9
Prerequisite edges	94
Average credits per course	3.42
Missing prerequisite links	0
Unknown requirement-code hits	0

4 Results

4.1 Quantitative Summary

Table 1 reports key metrics from the latest run.

4.2 Delivered System Features

The following deliverables were completed and validated in the current version:

- Student mode and advanced mode toggles for clean navigation.
- Policy-filtered major/minor options for institutional constraints.
- Year-semester structured prerequisite graphs with readable labels.
- Semester transition summaries for better planning visibility.
- Constrained term-by-term planner with blocked-course diagnostics.
- Major-minor combination simulator for comparative pathway analysis.
- Data quality checks and pathway validation reports.

4.3 Visual Analytics and Plots

Figure 2 shows the course distribution by semester and year, while Fig. 3 shows subject-level and prerequisite structure patterns.

4.4 Dashboard Outcome

The upgraded dashboard improves practical usability in three ways:

- Cleaner student-first navigation with optional advanced tabs.
- Better graph readability via consistent legends, role-aware colors, and transition summaries.
- Cleaner module separation (UI vs. graph logic vs. validation) to support testing and maintainable iteration.

In student testing scenarios, the planner can surface blocked courses with unsatisfied prerequisites and propose semester-wise alternatives under credit and load constraints.

For readability, high-resolution dashboard screenshots are included in the Appendix as full-width figures (instead of compact side-by-side thumbnails).

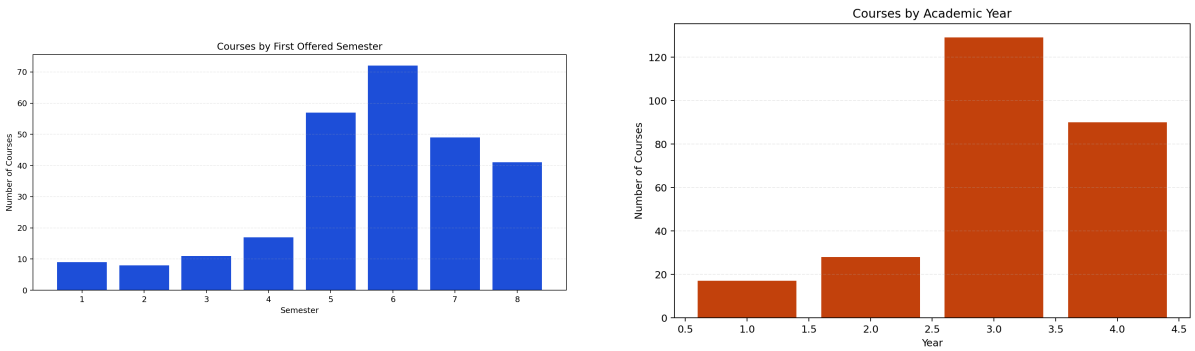

Figure 2: Course availability distribution over semester and academic year.

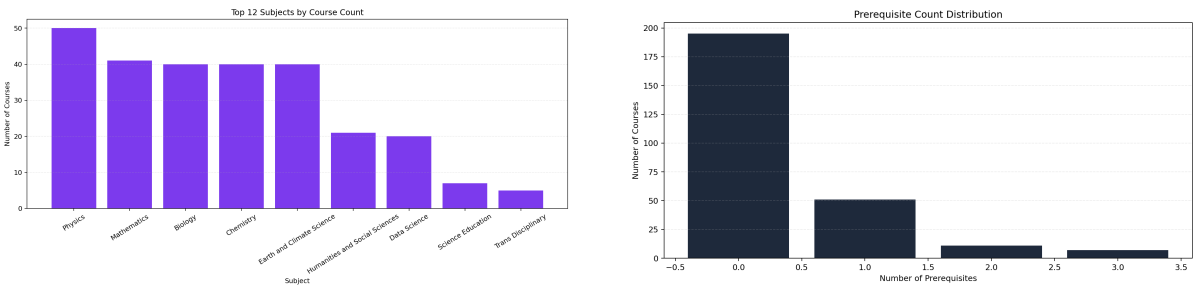

Figure 3: Subject concentration and prerequisite count structure.

4.5 Discussion of Outcomes

The final dashboard is not only visually cleaner but also operationally more reliable. Key reliability and usability outcomes include:

- No blocking data-quality issues in the current dataset snapshot.
- Stable headless startup and compile checks on the final codebase.
- Structured validation outputs that support testing and correctness.
- Better student readability through reduced clutter and clearer graph semantics.

5 Conclusion and Outlook

Curriculum Graph Studio now functions as a complete planning and analytics stack: data quality checks, dependency graphs, constrained planning, pathway validation, and a student-friendly dashboard UI. The most significant contribution is the combination of graph-theoretic logic with a student-friendly interaction layer, which makes technical analytics actionable for academic decision-making.

Future work includes:

- personalized pathway recommendations based on student goals,
- what-if simulation for delayed/failed prerequisites,
- integration with institutional enrollment systems,
- longitudinal evaluation of advising outcomes.

10.2 Algorithms

Algorithm 1 Constrained Semester Planner

Require: Directed graph G, course index I, start semester s_0, term caps

Ensure: Semester plan P and blocked set B

Initialize completed set C from known history
for $s = s_0$ to planning horizon **do**
  Find feasible set $F_s = \{c \mid c \in \mathcal{O}(s) \wedge pred(c) \subseteq C\}$
  Rank F_s by priority and downstream dependency impact
  Select courses under course-count and credit caps
  Add selected courses to $P[s]$ and update C
end for
$B \leftarrow V(G) \setminus C$
return P, B
